# ABSTRACT

Plagiarism detection has become an essential requirement in educational institutions, publishing organizations, and digital content platforms because of the rapid growth of online information. Instructors, editors, and publishers regularly examine short documents such as essays, assignments, abstracts, reports, and examination answers to ensure the originality of submitted content. Traditional plagiarism detection systems are often limited to identifying exact text matches and may fail to recognize content that has been modified through paraphrasing, word substitution, or sentence reorganization. As a result, there is a growing need for a more reliable system capable of identifying different forms of copied content while maintaining high accuracy and efficiency.

The proposed **Word-Level Plagiarism Checker for Short Documents** addresses this challenge by analyzing documents at the word level rather than depending solely on sentence-based comparisons. The system compares a submitted document with a reference corpus and identifies exact matches, reordered phrases, and lightly paraphrased content. The detection process includes several stages, including preprocessing, tokenization, stop-word removal, stemming, indexing, similarity measurement, and plagiarism analysis. By examining word sequences and contextual relationships, the system can identify similarities that are often overlooked by conventional plagiarism detection techniques. It also generates a comprehensive report that highlights plagiarized sections, calculates similarity scores, and identifies the original source of each matched passage.

Another important feature of the proposed system is its ability to operate efficiently without relying on prebuilt library data structures. Custom algorithms and data structures are implemented to improve processing speed and provide greater flexibility in document analysis. This approach makes the system suitable for interactive applications where quick responses are required. The proposed plagiarism checker can be applied in educational institutions, research environments, publishing companies, and online learning platforms to promote academic integrity and encourage the creation of original content. Experimental results indicate that the system provides accurate plagiarism detection while maintaining computational efficiency, making it a practical and scalable solution for short-document analysis.
